

Indoor electrical distribution box power supply

Article Overview

The power supply for an indoor electrical distribution box comes from the main electrical service line, typically connected to the utility grid or a transformer.

Source of Power

An indoor electrical distribution box, also known as a distribution panel or breaker panel, receives electricity from the main power supply of the building. This supply originates from the utility company, which generates electricity at power plants and transmits it through high-voltage transmission lines to local substations. At the substation, the voltage is stepped down using transformers to a safer level suitable for residential or commercial use, and then delivered to the building via service lines .

Connection to the Distribution Box

The main service line enters the building and connects to the main switch or circuit breaker inside the distribution box. From there, electricity is divided into multiple circuits that supply power to different areas, such as lighting, outlets, and appliances. Each circuit is protected by circuit breakers or fuses, which prevent overloads or short circuits .

Residential vs Commercial Supply

- o Residential buildings usually receive single-phase or split-phase power at standard voltages (e.g., 120/240V in the U.S.) from the utility transformer.
- o Commercial or industrial buildings may receive three-phase power at higher voltages, which is stepped down by transformers before entering the distribution box .

Safety and Regulation

The distribution box not only distributes power but also ensures safety. Protective devices like MCBs, fuses, and RCDs monitor the current and disconnect circuits if abnormal conditions occur, preventing damage to equipment and reducing fire risk . In summary, the indoor electrical distribution box is powered by the main service line from the utility, which passes through transformers and meters before entering the building. The box then safely distributes electricity to all circuits while providing protection against electrical faults.

The distribution box serves as the load centre and distributor of electrical power. A distribution box ensures
